Lecture 5 —  $\epsilon$ -NFA

Hakjoo Oh 2017 Spring

### NFA with $\epsilon$ -Transitions

NFAs with transitions on  $\epsilon$  allowed.

$$M = (\{q_0, q_1, q_2\}, \{a\}, \delta, q_0, \{q_2\})$$
  
 $\delta(q_0, a) = \{q_1\}$   $\delta(q_0, \epsilon) = \emptyset$   
 $\delta(q_1, a) = \emptyset$   $\delta(q_1, \epsilon) = \{q_2\}$   
 $\delta(q_2, a) = \emptyset$   $\delta(q_2, \epsilon) = \{q_0\}$ 

## NFA with $\epsilon$ -Transitions

### **Definition**

An  $\epsilon$ -NFA:

$$M=(Q,\Sigma,\delta,q_0,F)$$

#### where

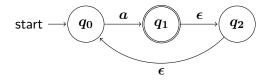

- Q: a finite set of states
- ullet  $\Sigma$ : a finite set of *input symbols* (or input alphabet)
- $q_0 \in Q$ : the initial state
- ullet  $F\subseteq Q$ : a set of final states
- $\delta: Q \times (\Sigma \cup \{\epsilon\}) \to 2^Q$ : transition function

### **Extended Transition Function**

Informal definition of  $\delta^*: Q \times \Sigma^* \to 2^Q$ :

#### **Definition**

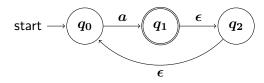

For an  $\epsilon$ -NFA, the extended transition function is defined so that  $\delta^*(q_i,w)$  contains  $q_j$  iff there is a path in the transition graph from  $q_i$  to  $q_j$  labeled by w.

- $\delta^*(q_1, a) =$
- $\delta^*(q_2,\epsilon) =$
- $\delta^*(q_2, aa) =$

# **Epsilon-Closures**

 $\mathrm{EClose}(q)$ : the set of reachable states by  $\epsilon$ -transitions.

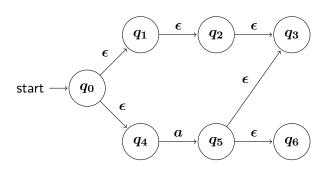

- ECLOSE $(q_0) =$
- ECLOSE $(q_1) =$
- ECLOSE $(q_2) =$

### Defined recursively:

- ullet (Basis): ECLOSE(q) includes q
- (Induction): If state p is in ECLOSE(q), and there is a transition from state p to state r labeled  $\epsilon$ , then r is in ECLOSE(q).

# Example

$$ext{EClose}(q_0) = \{q_0, q_1, q_2, q_3, q_4\}$$
  $ext{EClose}(\{q_0, q_5\}) = \{q_0, q_1, q_2, q_3, q_4, q_5, q_6\}$ 

## Formal Definition of $\delta^*$

$$\delta^*:Q imes \Sigma^* o 2^Q$$

• (Basis)

$$\delta^*(q,\epsilon) = \mathrm{EClose}(q)$$

(Induction)

$$\delta^*(q, ua) = \text{EClose}(\bigcup_{s_i \in \delta^*(q, u)} \delta(s_i, a))$$

# Language of $\epsilon$ -NFA

An  $\epsilon$ -NFA  $M=(Q,\Sigma,\delta,q_0,F)$  accepts a string w if

$$\delta^*(q_0,w)\cap F
eq\emptyset$$

and the language of automaton  $oldsymbol{M}$  is defined as follows:

$$L(M) = \{w \in \Sigma^* \mid \delta^*(q_0, w) \cap F \neq \emptyset\}$$

#### From $\epsilon$ -NFA to DFA

Given an  $\epsilon$ -NFA  $E=(Q_E,\Sigma,\delta_E,q_0,F_E)$ , define a DFA:

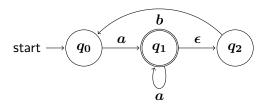

$$D = (Q_D, \Sigma, \delta_D, q_D, F_D)$$

- $Q_D = \{S \subseteq Q_E \mid S = \text{EClose}(S)\}$
- $q_D = \text{EClose}(q_0)$
- $\bullet \ F_D = \{S \in Q_D \mid S \cap F_E \neq \emptyset\}$
- ullet For each  $S\in Q_D$  and input symbol  $a\in \Sigma$ :

$$\delta_D(S,a) = ext{ECLOSE}(igcup_{p \in S} \delta_E(p,a))$$

## Exercise

Convert the following  $\epsilon$ -NFA into an equivalent DFA.

# Equivalence of $\epsilon$ -NFA and DFA

#### Theorem

A language L is accepted by some  $\epsilon$ -NFA if and only if L is accepted by some DFA.

### Proof.

- (If) Easy.
- (Only if) Exercise.
